AP-08: *JavaBeans*

Overview

- Kinds of components in Java
- JavaBeans: design and deployment
  - Properties
    - Property design pattern
  - Events
    - Connection-oriented programming
    - Observer design pattern
  - Serialization
  - Jar
  - Introspection (InfoBeans)

➜ Chapter 14, sections 14.1, 14.3 and 14.5 of *Component Software: Beyond Object-Oriented Programming. C. Szyperski, D. Gruntz, S. Murer, Addison-Wesley, 2002*.

➜ [The JavaBeans API Specification](#), sections 1, 2, 6, 7 and 8.

https://www.oracle.com/technetwork/java/javase/ documentation/spec-136004.html

Components in Java SE (Standard Edition): Java Beans

Java Language	Java Language					
Tools & Tool APIs	java	javac	javadoc	jar	javap	Scripting
	Security	Monitoring	JConsole	VisualVM	JMC	JFR
	JPDA	JVM TI	IDL	RMI	Java DB	Deployment
	Internationalization		Web Services		Troubleshooting	
Deployment	Java Web Start			Applet / Java Plug-in		
	JavaFX					
User Interface Toolkits	Swing		Java 2D		AWT	Accessibility
	Drag and Drop		Input Methods		Image I/O	Print Service / Sound
Integration Libraries	IDL	JDBC	JNDI	RMI	RMI-IIOP	Scripting
Other Base Libraries	Beans	Security		Serialization	Extension Mechanism	
	JMX	XML JAXP		Networking	Override Mechanism	
	JNI	Date and Time		Input/Output	Internationalization	
	lang and util					
lang and util Base Libraries	Math	Collections		Ref Objects	Regular Expressions	
	Logging	Management		Instrumentation	Concurrency Utilities	
	Reflection	Versioning		Preferences API	JAR	Zip
Java Virtual Machine	Java HotSpot Client and Server VM					

JDK — JRE — Compact Profiles — Java SE API

3

Other Java Distributions

- Java EE (Enterprise Edition)
  - Suite of specifications for application servers
  - Around 20 implementations available
  - Reference implementation: Oracle Glassfish
- Java ME (Micro Edition)
  - embedded and mobile devices, e.g. micro-controllers, sensors, gateways, mobile phones, personal digital assistants (PDAs), TV set-top boxes, printers…

# Components in Java EE (Enterprise Edition)
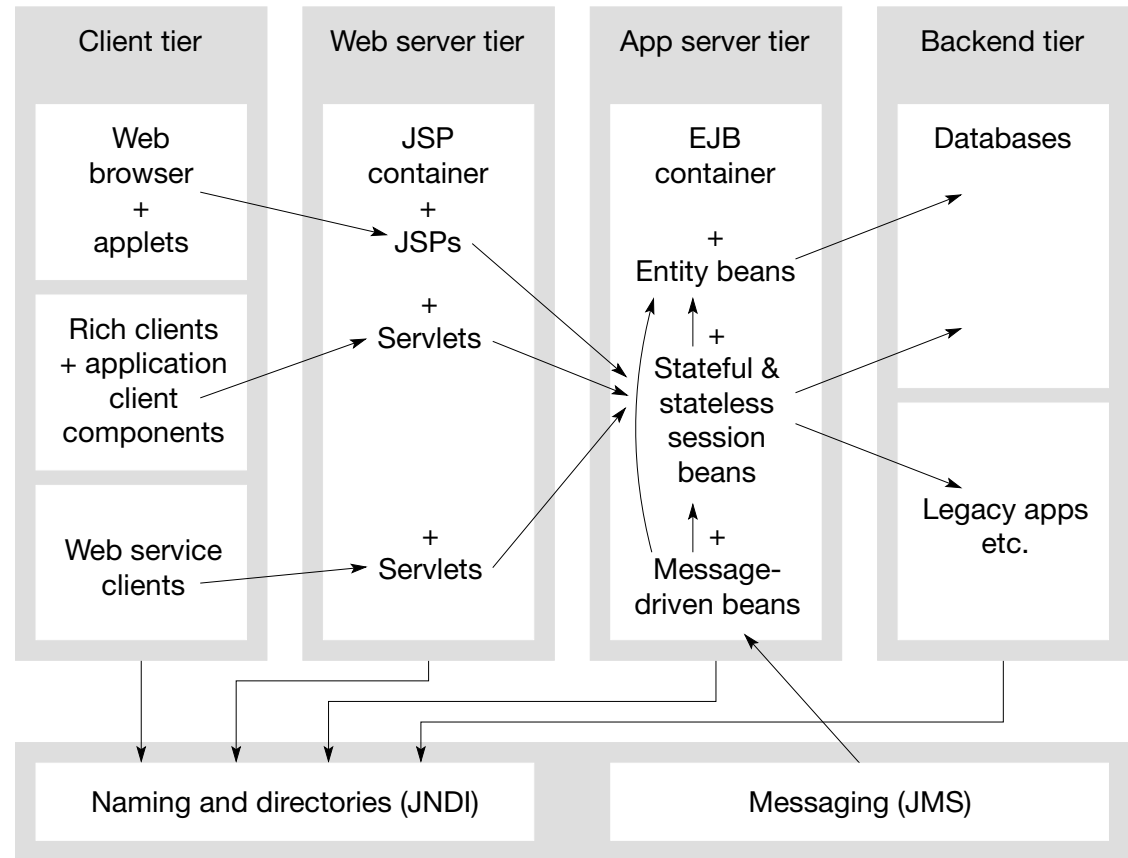

Client side
- JavaBeans
- Applets
- Application Components

Web server tier
- Servlets
- JSPs

Application tier:
- Stateless session EJB
- Stateful session EJB
- Entity EJB
- Message-driven EJB

Client-Side Presentation	Server-Side Presentation	Server-Side Business Logic	Enterprise Information System
Browser Pure HTML Java Applet	**Web Server** JSP Java Servlet XML Web Services	**EJB Container** EJB EJB Web Services Web Services	
Desktop Java Application			
Other Devices J2EE Client	J2EE Platform	J2EE Platform

Components in Java EE (Enterprise Edition)

Client side
- JavaBeans
- Applets
- Application Components

Web server tier
- Servlets
- JSPs

Application tier:
- Stateless session EJB
- Stateful session EJB
- Entity EJB
- Message-driven EJB

Client tier	Web server tier	App server tier	Backend tier
Web browser + applets	JSP container + JSPs	EJB container + Entity beans	Databases
Rich clients + application client components	+ Servlets	+ Stateful & stateless session beans	
Web service clients	+ Servlets	Message-driven beans	Legacy apps etc.

Naming and directories (JNDI)　　　　Messaging (JMS)

The JavaBeans API (1996)

Goal: to define a software component model for Java, allowing vendors to create and ship Java components that can be composed together into applications by end users.

Design goals:

- **Granularity**: from small (eg. a button in a GUI) to medium (eg. a spreadsheet as part of al larger document)
  - Similar to Microsoft's OLE Control or ActiveX APIs
- **Portability**: Ok in Java based application servers.Bridges defined to other component models (like OpenDoc, OLE/COM/ ActiveX)
- **Uniformity and Simplicity**: The API should be simple to be supported on different platforms. Strong support for small component, with reasonable defaults.

What are Java Beans?

"A Java Bean is a **reusable software component** that can be **manipulated visually** in a **builder tool**."

- **Sample tools:** builders for web pages, visual applications, GUI layout, server applications. Also document editors.

- A bean typically has a GUI representation, but not necessarily
  - Invisible beans

- Any Java class can be recognized as a bean in a tool provided that
  - Has a public default constructor (no arguments)
  - Implements the interface `java.io.Serializable`
  - Is in a **jar** file with *manifest file* containing
    `Java-Bean: True` (Really needed?)

# JavaBeans as Software Components

- Beans are binary building blocks (class files)
- Development vs. deployment (customization)
- Beans can be assembled to build a new bean or a new application, applet, … writing glue code to wire beans together
- Client side bean vs. beans for business logic process in MVC on server
- Beans on server are not visible
Sample Reusable Components

Button Beans
Slider Bean
An application constructed from Beans

JavaBeans common features

- Support for **properties**, both for customization and for programmatic use
- Support for **events**: simple communication metaphor that can be used to connect several beans
- Support for **customization**: in the builder the user can customize the appearance and behaviour of the bean
- Support for **persistence**: a bean can be customized in an application builder and then have its customized state saved away and reloaded later
- Support for **introspection**: a builder tool can analyze how the bean works

Emphasis on GUI, but textual programming also possible using the existing API

Design time vs. run-time

- A bean must be able to run in the *design environment* of a builder tool providing means to the user to customize aspect and behaviour
- At run-time there is less need for customization
- Possible solution: design-time information for customization is separated form run-time information, and not loaded at run-time
  - **<BeanName>BeanInfo.java class**

Simple Properties

- Discrete named attributes that can affect a bean instance's appearance or behaviour

- Property X (and its type) determined by public setter (setX) and /or getter (getX) methods

- Can be changed at design time (customization) or run-time (application logic)

- Example property: **background**

```
public java.awt.Color getBackground ();
public void setBackground (java.awt.Color color);
```
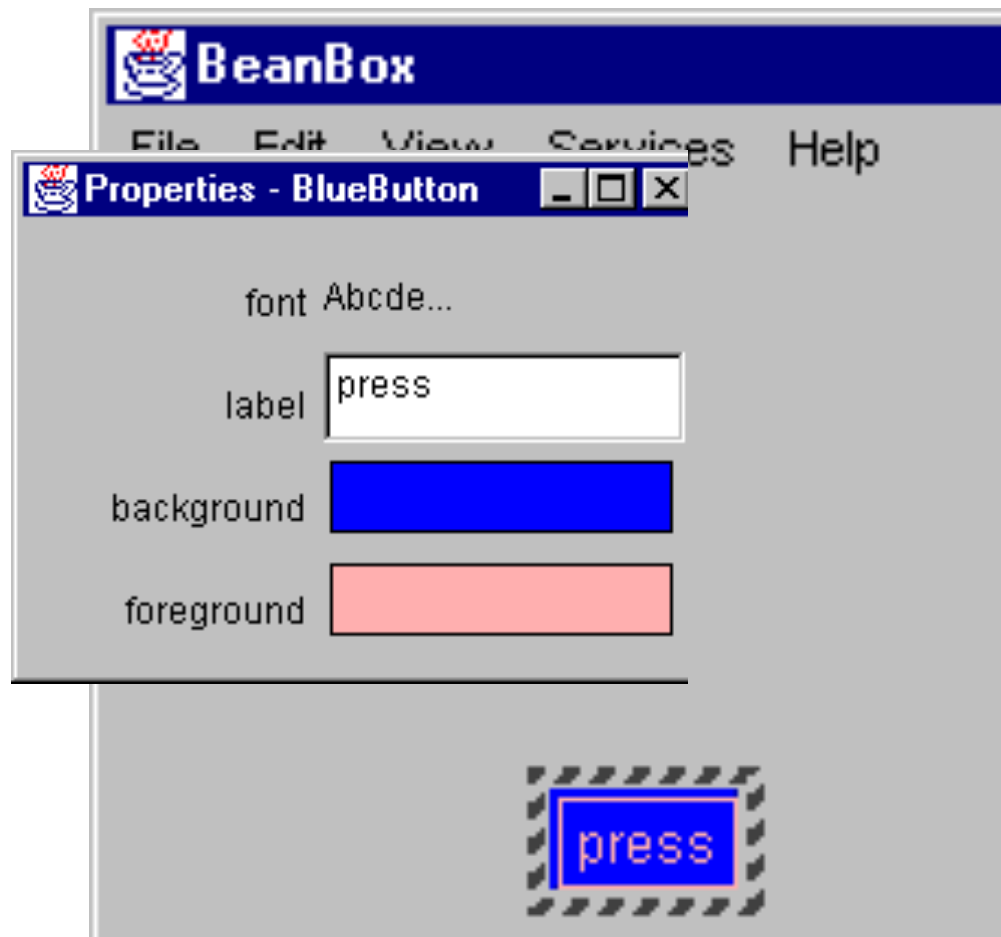

How can a builder identify the properties of a bean?

Introspection

- Process of analyzing a bean to determine the capability

- Allows application builder tool to present info about a component to software designers

- *<BeanName>BeanInfo* class to explicitly infer info on a bean

- Implicit method: based on **reflection**, **naming conventions**, and **design patterns**

Design Pattern for Simple Properties

- From pair of methods:

```
public <PropertyType> get<PropertyName>();

public void set<PropertyName>(<PropertyType> a);
```

infer existence of property **propertyName** of type **PropertyType**

- Example:

```
public java.awt.Color getBackground ();
public void setBackground (java.awt.Color color);
```

- If only the getter (setter) method is present then the property is read-only (write-only)

Pattern for Indexed Properties

- If a property is an array, setter/getter methods can take an index or the whole array

```
public java.awt.Color getSpectrum (int index);
public java.awt.Color[] getSpectrum ();
public void setSpectrum (int index, java.awt.Color color);
public void setSpectrum (java.awt.Color[] colors);
```

- From these methods, by introspection the builder infers the existence of property **spectrum** of type **java.awt.Color[]**

Bound and Constrained Property

- A ***bound property*** generates an event when the property is changed

- A ***constrained property*** can only change value if none of the registered observers "poses a veto"

➔ We discuss them after the event-based communication mechanism

# Connection-oriented programming

- Paradigm for gluing together components in a builder tool

- Based on the **Observer** design pattern

- Adequate for GUIs

Pattern: **Observer** (Behavioral)
aka **Publish-Subscribe**

Name: Observer

Problem: Define a one-to-many dependency among objects so that when one object changes state, all of its dependents are notified and updated automatically.

```
+--------------------+    Observers    +--------------------+
|     *Subject*      |---------------->|     *Observer*     |
+--------------------+  1            *  +--------------------+
| +Attach(in Observer)                 | +Update()          |
| +Detach(in Observer)                 +--------------------+
| +Notify()  o                         |
+--------------------+
```

For all o in observers {
    o->Update()
}

```
+--------------------+        Subject  +--------------------+
| **ConcreteSubject**|<----------------| **ConcreteObserver**|
+--------------------+                 +--------------------+
| –subjectState      |                 | –observerState     |
+--------------------+                 +--------------------+
| +GetState()  o     |                 | +Update()  o       |
| +SetState()        |                 +--------------------+
+--------------------+
```

Return subjectState

observerState =
    subject->GetState()

Events

- In Java the Observer pattern is based on Events and Event Listeners
- An **event** is an object created by an **event source** and propagated to the registered **event listeners**
- Multicast semantics by default: several possible listeners
- Unicast semantics (at most one listener) can be enforced by tagging the event source.

Design Pattern for Events

Based on methods for (un)registering listeners. From

```
public void add<EventListType>(<EventListType> a)
public void remove<EventListType>(<EventListType> a)
```

infer that the object is source of an event; the name is extracted from **EventListType**.

Example: from

```
public void addUserSleepsListener (UserSleepsListener l);
public void removeUserSleepsListener (UserSleepsListener l);
```

infers that the class generates a **UserSleeps** event

Unicast event sources

- Unicast sematics is assumed if the **add** method is declared to throw **java.util.TooManyListenersException**
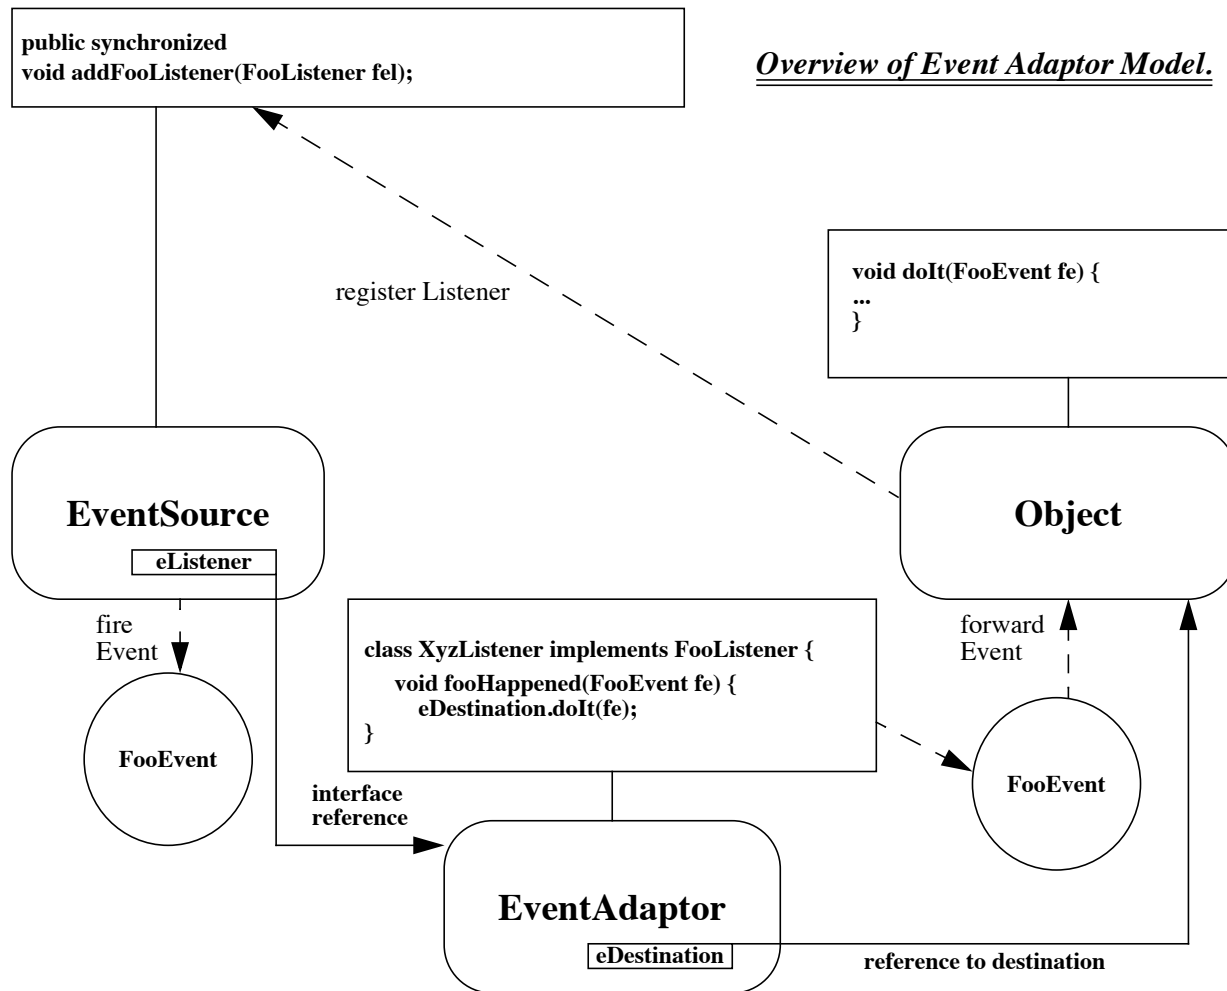

- Example:

```
public void addJackListener(JackListener t)
throws java.util.TooManyListenersException;

public void removeJackListener(JackListener t);
```

defines a unicast event source for the "JackListener" interface.

Event Adaptors

- Placed between the event source and a listener
- Is at the same time listener and source
- Examples of uses of adaptors:
  - Implementing an event queuing mechanism between sources and listeners.
  - Acting as a filter.
  - Demultiplexing multiple event sources onto a single event listener.
  - Acting as a generic "wiring manager" between sources and listeners.

Event Adaptors: general architecture

public synchronized
void addFooListener(FooListener fel);

__Overview of Event Adaptor Model.__

register Listener

void doIt(FooEvent fe) {
...
}

EventSource

eListener

fire
Event

FooEvent

class XyzListener implements FooListener {

    void fooHappened(FooEvent fe) {
        eDestination.doIt(fe);
}

interface
reference

Object

forward
Event

FooEvent

EventAdaptor

eDestination

reference to destination

Event adaptors example:
Demultiplexing multiple event sources

OK Button → buttonPushed(PBEvent pbe)

OKButtonAdaptor

Dialog Box

```
buttonPushed(PBEvent pbe) {
    dialog.doOKAction();
}
```

```
doOKAction() {
    // ...
}
```

okButton.addPBListener(okButtonAdaptor)

cancelButton.addPBListener(cancelButtonAdaptor)

CancelButtonAdaptor

```
doCancelAction() {
    // ...
}
```

```
buttonPushed(PBEvent pbe) {
    dialog.doCancelAction();
}
```

Cancel Button → buttonPushed(PBEvent pbe)

Back to Bound Properties

- Can generate an event when the property is changed
- The event is of type **PropertyChangeEvent** and is sent to objects that previously registered an interest in receiving such notifications
- Bean with bound property: *event source*
- Bean implementing listener: *event target*
- Helper classes in the API to simplify implementation

Implement Bound Property in a Bean

1. Import **java.beans** package

2. Instantiate a **PropertyChangeSupport** helper object
   private PropertyChangeSupport changes = new PropertyChangeSupport(this);

3. Implement methods to maintain the property change listener list:

```
public void
  addPropertyChangeListener(PropertyChangeListener l)
  { changes.addPropertyChangeListener(l);}
```

(also **removePropertyChangeListener** method is needed)

Implement Bound Property in a Bean (cont.)

4. Modify a property's setter method to fire a property change event when the property is changed.

```java
public void setX(int newX){
    int oldx = x;
    x = newX;
    changes.firePropertyChange("x", oldX, newX);
}
```

Implement Bound Property Listener

1. Listener bean must implement the interface **PropertyChangeListner**

    ```
    public class MyLstnr implements
                PropertyChangeListener, Serializable
    ```

2. It must override the method

    ```
    public abstract void
       propertyChange(PropertyChangeevent evt)
    ```

3. Sample registration:
    ```
    Button button = new OurButton();
    MyLstnr lis = new MyLstnr();
    button.addPropertyChangeListener(lis);
    ```

Constrained Property

- It generates an event when an attempt is made to change it value

- The event type is **PropertyChangeEvent**

- The event is sent to objects that previously registered an interest in receiving such notification

- Those other objects have the ability to veto the proposed change by raising an exception

- This allows a bean to operate differently according to the runtime environment

Three Parts in Implementation of Constrained Property

1. Source bean containing one or more constrained properties

2. Listener objects that implement the **`VetoableChangeListener`** interface. This object either accepts or rejects the proposed change. The change is rejected by raising a **PropertyVetoException**

3. **`PropertyChangeEvent`** object containing property name, old value, new value.

Implement Constrained Property in a Bean

The bean containing the constrained property must:

1. Import the **`java.beans`** package

2. Instantiate a **`VetoableChangeSupport`** object:

```
private VetoableChangeSupport vetos =
        new VetoableChangeSupport(this);
```

3. Implement methods to maintain the listener list:
```
public void
    addVetoableChangelistener(VetoableChangelistener l)
    {   vetos.addVetoableChangeListener(l);}
```

4. and similarly for **`removeVetoableChangelistener`**

Implement Constrained Property in a Bean (cont.)

5. Write a property's setter method to fire a property change event:

```
public void setX(int newX)
  {   int oldX = X;
      try{
          vetos.fireVetoableChange("x", oldX, newX);
          // if no veto there
          X = newX;
          // add here code to notify change, if needed
      } catch(PropertyVetoException e){
          // code to be executed if
          // change is rejected by somebody
      }
  }
```

Implementing Constrained Property Listeners

1. Implements the **`VetoableChangeListener`** interface which has an abstract method
   `void vetoChange(PropertyChangeEvent evt)`

2. Override this abstract method. This is the method that will be called by the source bean on each object in the listener list kept by the **`vetoableChangeSupport`** object

3. If the listener wants to forbid the change described in **`evt`**, it should raise a **PropertyVetoException**. Otherwise simply return.

Summary

- JavaBean is a platform-neutral component architecture for reusable software component

- It is a black box component to be used to build large component or application

- Property, method, event, introspector, customizer are parts of the JavaBean API
